See www.db-book.com for conditions on re-use

Advanced SQL

- SQL Data Types and Schemas
- Integrity Constraints
- Authorization
- Embedded SQL
- Dynamic SQL
- Functions and Procedural Constructs**
- Recursive Queries**
- Advanced SQL Features**

Database System Concepts - 5th Edition, June 15, 2005 4.2 ©Silberschatz, Korth and Sudarshan

Built-in Data Types in SQL

- **date**: Dates, containing a (4 digit) year, month and date
 - Example: **date** '2005-7-27'
- **time**: Time of day, in hours, minutes and seconds.
 - Example: **time** '09:00:30' **time** '09:00:30.75'
- **timestamp**: date plus time of day
 - Example: **timestamp** '2005-7-27 09:00:30.75'
- **interval**: period of time
 - Example: **interval** '1' day
 - Subtracting a date/time/timestamp value from another gives an interval value
 - Interval values can be added to date/time/timestamp values

Database System Concepts - 5th Edition, June 15, 2005 4.3 ©Silberschatz, Korth and Sudarshan

Build-in Data Types in SQL (Cont.)

- Can extract values of individual fields from date/time/timestamp
 - Example: **extract** (year from r.starttime)
- Can cast string types to date/time/timestamp
 - Example: **cast** <string-valued-expression> **as date**
 - Example: **cast** <string-valued-expression> **as time**

Database System Concepts - 5th Edition, June 15, 2005 4.4 ©Silberschatz, Korth and Sudarshan

User-Defined Types

- **create type** construct in SQL creates user-defined type

```
create type Dollars as numeric (12,2) final
```
- **create domain** construct in SQL-92 creates user-defined domain types

```
create domain person_name char(20) not null
```
- Types and domains are similar. Domains can have constraints, such as **not null**, specified on them.

Database System Concepts - 5th Edition, June 15, 2005 4.5 ©Silberschatz, Korth and Sudarshan

Domain Constraints

- **Domain constraints** are the most elementary form of integrity constraint. They test values inserted in the database, and test queries to ensure that the comparisons make sense.
- New domains can be created from existing data types
 - Example: **create domain Dollars numeric(12, 2)**
create domain Pounds numeric(12,2)
- We cannot assign or compare a value of type Dollars to a value of type Pounds.
 - However, we can convert type as below
(**cast r.A as Pounds**)
(Should also multiply by the dollar-to-pound conversion-rate)

Database System Concepts - 5th Edition, June 15, 2005 4.6 ©Silberschatz, Korth and Sudarshan

Large-Object Types

- Large objects (photos, videos, CAD files, etc.) are stored as a *large object*.
 - **blob**: binary large object -- object is a large collection of uninterpreted binary data (whose interpretation is left to an application outside of the database system)
 - **clob**: character large object -- object is a large collection of character data
 - When a query returns a large object, a pointer is returned rather than the large object itself.

Database System Concepts - 5th Edition, June 15, 2005 4.7 ©Silberschatz, Korth and Sudarshan

Integrity Constraints

- Integrity constraints guard against accidental damage to the database, by ensuring that authorized changes to the database do not result in a loss of data consistency.
 - A checking account must have a balance greater than \$10,000.00
 - A salary of a bank employee must be at least \$4.00 an hour
 - A customer must have a (non-null) phone number

Database System Concepts - 5th Edition, June 15, 2005 4.8 ©Silberschatz, Korth and Sudarshan

Constraints on a Single Relation

- **not null**
- **primary key**
- **unique**
- **check (P)**, where P is a predicate

Database System Concepts - 5th Edition, June 15, 2005 4.9 ©Silberschatz, Korth and Sudarshan

Not Null Constraint

- Declare *branch_name* for *branch* is **not null**
`branch_name char(15) not null`
- Declare the domain *Dollars* to be **not null**
`create domain Dollars numeric(12,2) not null`

Database System Concepts - 5th Edition, June 15, 2005 4.10 ©Silberschatz, Korth and Sudarshan

The Unique Constraint

- **unique (A_1, A_2, \dots, A_m)**

The unique specification states that the attributes

$$A_1, A_2, \dots, A_m$$

Form a candidate key.

Candidate keys are permitted to be null (in contrast to primary keys).

Database System Concepts - 5th Edition, June 15, 2005 4.11 ©Silberschatz, Korth and Sudarshan

The check clause

- **check (P)**, where P is a predicate

Example: Declare *branch_name* as the primary key for *branch* and ensure that the values of *assets* are non-negative.

```
create table branch
(branch_name char(15),
 branch_city char(30),
 assets integer,
 primary key (branch_name),
 check (assets >= 0))
```

Database System Concepts - 5th Edition, June 15, 2005 4.12 ©Silberschatz, Korth and Sudarshan

The check clause (Cont.)

- The **check** clause in SQL-92 permits domains to be restricted:
 - Use **check** clause to ensure that an `hourly_wage` domain allows only values greater than a specified value.

```
create domain hourly_wage numeric(5,2)
constraint value_test check(value >= 4.00)
```
 - The domain has a constraint that ensures that the `hourly_wage` is greater than 4.00
 - The clause **constraint** `value_test` is optional; useful to indicate which constraint an update violated.

Database System Concepts - 5th Edition, June 15, 2005 4.13 ©Silberschatz, Korth and Sudarshan

Referential Integrity

- Ensures that a value that appears in one relation for a given set of attributes also appears for a certain set of attributes in another relation.
 - Example: If "Perryridge" is a branch name appearing in one of the tuples in the `account` relation, then there exists a tuple in the `branch` relation for branch "Perryridge".
- Primary and candidate keys and foreign keys can be specified as part of the SQL **create table** statement:
 - The primary key clause lists attributes that comprise the primary key.
 - The unique key clause lists attributes that comprise a candidate key.
 - The foreign key clause lists the attributes that comprise the foreign key and the name of the relation referenced by the foreign key. By default, a foreign key references the primary key attributes of the referenced table.

Database System Concepts - 5th Edition, June 15, 2005 4.14 ©Silberschatz, Korth and Sudarshan

Referential Integrity in SQL – Example

```
create table customer
(customer_name char(20),
 customer_street char(30),
 customer_city char(30),
 primary key (customer_name))

create table branch
(branch_name char(15),
 branch_city char(30),
 assets numeric(12,2),
 primary key (branch_name))
```

Database System Concepts - 5th Edition, June 15, 2005 4.15 ©Silberschatz, Korth and Sudarshan

Referential Integrity in SQL – Example (Cont.)

```
create table account
(account_number char(10),
 branch_name char(15),
 balance integer,
 primary key (account_number),
 foreign key (branch_name) references branch)

create table depositor
(customer_name char(20),
 account_number char(10),
 primary key (customer_name, account_number),
 foreign key (account_number) references account,
 foreign key (customer_name) references customer)
```

Database System Concepts - 5th Edition, June 15, 2005 4.16 ©Silberschatz, Korth and Sudarshan

Assertions

- An **assertion** is a predicate expressing a condition that we wish the database always to satisfy.
- An assertion in SQL takes the form

```
create assertion <assertion-name> check <predicate>
```
- When an assertion is made, the system tests it for validity, and tests it again on every update that may violate the assertion
 - This testing may introduce a significant amount of overhead; hence assertions should be used with great care.
- Asserting for all $X, P(X)$ is achieved in a round-about fashion using not exists X such that not $P(X)$

Database System Concepts - 5th Edition, June 15, 2005 4.17 ©Silberschatz, Korth and Sudarshan

Assertion Example

- Every loan has at least one borrower who maintains an account with a minimum balance or \$1000.00

```
create assertion balance_constraint check
(not exists (
select *
from loan
where not exists (
select *
from borrower, depositor, account
where loan.loan_number = borrower.loan_number
and borrower.customer_name = depositor.customer_name
and depositor.account_number = account.account_number
and account.balance >= 1000)))
```

Database System Concepts - 5th Edition, June 15, 2005 4.18 ©Silberschatz, Korth and Sudarshan

Assertion Example

- The sum of all loan amounts for each branch must be less than the sum of all account balances at the branch.

```

create assertion sum_constraint check
(not exists (select *
from branch
where (select sum(amount)
from loan
where loan.branch_name =
branch.branch_name )
>= (select sum (amount)
from account
where loan.branch_name =
branch.branch_name )))

```

Database System Concepts - 5th Edition, June 15, 2005 4.19 ©Silberschatz, Korth and Sudarshan

Authorization

Forms of authorization on parts of the database:

- Read** - allows reading, but not modification of data.
- Insert** - allows insertion of new data, but not modification of existing data.
- Update** - allows modification, but not deletion of data.
- Delete** - allows deletion of data.

Forms of authorization to modify the database schema (covered in Chapter 8):

- Index** - allows creation and deletion of indices.
- Resources** - allows creation of new relations.
- Alteration** - allows addition or deletion of attributes in a relation.
- Drop** - allows deletion of relations.

Database System Concepts - 5th Edition, June 15, 2005 4.20 ©Silberschatz, Korth and Sudarshan

Authorization Specification in SQL

- The **grant** statement is used to confer authorization
grant <privilege list>
on <relation name or view name> **to** <user list>
- <user list> is:
 - a user-id
 - public**, which allows all valid users the privilege granted
 - A role (more on this in Chapter 8)
- Granting a privilege on a view does not imply granting any privileges on the underlying relations.
- The grantor of the privilege must already hold the privilege on the specified item (or be the database administrator).

Database System Concepts - 5th Edition, June 15, 2005 4.21 ©Silberschatz, Korth and Sudarshan

Privileges in SQL

- select**: allows read access to relation, or the ability to query using the view
 - Example: grant users U_1 , U_2 , and U_3 **select** authorization on the *branch* relation:
grant select on branch to U_1 , U_2 , U_3
- insert**: the ability to insert tuples
- update**: the ability to update using the SQL update statement
- delete**: the ability to delete tuples.
- all privileges**: used as a short form for all the allowable privileges more in Chapter 8

Database System Concepts - 5th Edition, June 15, 2005 4.22 ©Silberschatz, Korth and Sudarshan

Revoking Authorization in SQL

- The **revoke** statement is used to revoke authorization.
revoke <privilege list>
on <relation name or view name> **from** <user list>
- Example:
revoke select on branch from U_1 , U_2 , U_3
- <privilege-list> may be **all** to revoke all privileges the revokee may hold.
- If <revokee-list> includes **public**, all users lose the privilege except those granted it explicitly.
- If the same privilege was granted twice to the same user by different grantees, the user may retain the privilege after the revocation.
- All privileges that depend on the privilege being revoked are also revoked.

Database System Concepts - 5th Edition, June 15, 2005 4.23 ©Silberschatz, Korth and Sudarshan

Embedded SQL

- The SQL standard defines embeddings of SQL in a variety of programming languages such as C, Java, and Cobol.
- A language to which SQL queries are embedded is referred to as a **host language**, and the SQL structures permitted in the host language comprise *embedded SQL*.
- The basic form of these languages follows that of the System R embedding of SQL into PL/I.
- EXEC SQL** statement is used to identify embedded SQL request to the preprocessor
EXEC SQL <embedded SQL statement > END_EXEC
Note: this varies by language (for example, the Java embedding uses # SQL { ... };)

Database System Concepts - 5th Edition, June 15, 2005 4.24 ©Silberschatz, Korth and Sudarshan

Example Query

- From within a host language, find the names and cities of customers with more than the variable amount dollars in some account.
- Specify the query in SQL and declare a *cursor* for it

```
EXEC SQL
  declare c cursor for
  select customer_name, customer_city
  from depositor, customer, account
  where depositor.customer_name = customer.customer_name
     and depositor.account_number = account.account_number
     and account.balance > :amount
END_EXEC
```

Database System Concepts - 5th Edition, June 15, 2005 4.25 ©Silberschatz, Korth and Sudarshan

Embedded SQL (Cont.)

- The **open** statement causes the query to be evaluated
EXEC SQL **open** c END_EXEC
- The **fetch** statement causes the values of one tuple in the query result to be placed on host language variables.
EXEC SQL **fetch** c into :cn, :cc END_EXEC
Repeated calls to **fetch** get successive tuples in the query result
- A variable called SQLSTATE in the SQL communication area (SQLCA) gets set to '02000' to indicate no more data is available
- The **close** statement causes the database system to delete the temporary relation that holds the result of the query.
EXEC SQL **close** c END_EXEC

Note: above details vary with language. For example, the Java embedding defines Java iterators to step through result tuples.

Database System Concepts - 5th Edition, June 15, 2005 4.26 ©Silberschatz, Korth and Sudarshan

Updates Through Cursors

- Can update tuples fetched by cursor by declaring that the cursor is for update

```
declare c cursor for
select *
from account
where branch_name = 'Perryridge'
for update
```

- To update tuple at the current location of cursor *c*

```
update account
set balance = balance + 100
where current of c
```

Database System Concepts - 5th Edition, June 15, 2005 4.27 ©Silberschatz, Korth and Sudarshan

Dynamic SQL

- Allows programs to construct and submit SQL queries at run time.
- Example of the use of dynamic SQL from within a C program.

```
char * sqlprog = "update account
  set balance = balance * 1.05
  where account_number = ?"
EXEC SQL prepare dynprog from :sqlprog;
char account[10] = "A-101";
EXEC SQL execute dynprog using :account;
```

- The dynamic SQL program contains a ?, which is a place holder for a value that is provided when the SQL program is executed.

Database System Concepts - 5th Edition, June 15, 2005 4.28 ©Silberschatz, Korth and Sudarshan

ODBC and JDBC

- API (application-program interface) for a program to interact with a database server
- Application makes calls to
 - Connect with the database server
 - Send SQL commands to the database server
 - Fetch tuples of result one-by-one into program variables
- ODBC (Open Database Connectivity) works with C, C++, C#, and Visual Basic
- JDBC (Java Database Connectivity) works with Java

Database System Concepts - 5th Edition, June 15, 2005 4.29 ©Silberschatz, Korth and Sudarshan

ODBC

- Open DataBase Connectivity(ODBC) standard
 - standard for application program to communicate with a database server.
 - application program interface (API) to
 - › open a connection with a database,
 - › send queries and updates,
 - › get back results.
- Applications such as GUI, spreadsheets, etc. can use ODBC

Database System Concepts - 5th Edition, June 15, 2005 4.30 ©Silberschatz, Korth and Sudarshan

ODBC (Cont.)

- Each database system supporting ODBC provides a "driver" library that must be linked with the client program.
- When client program makes an ODBC API call, the code in the library communicates with the server to carry out the requested action, and fetch results.
- ODBC program first allocates an SQL environment, then a database connection handle.
- Opens database connection using SQLConnect(). Parameters for SQLConnect:
 - connection handle,
 - the server to which to connect
 - the user identifier,
 - password
- Must also specify types of arguments:
 - SQL_NTS denotes previous argument is a null-terminated string.

Database System Concepts - 5th Edition, June 15, 2005 4.31 ©Silberschatz, Korth and Sudarshan

ODBC Code

```

int ODBCexample()
{
    RETCODE error;
    HENV env; /* environment */
    HDBC conn; /* database connection */
    SQLAllocEnv(&env);
    SQLAllocConnect(&env, &conn);
    SQLConnect(conn, "aura.bell-labs.com", SQL_NTS, "avi", SQL_NTS,
               "avipasswd", SQL_NTS);
    { ... Do actual work ... }

    SQLDisconnect(conn);
    SQLFreeConnect(conn);
    SQLFreeEnv(env);
}

```

Database System Concepts - 5th Edition, June 15, 2005 4.32 ©Silberschatz, Korth and Sudarshan

ODBC Code (Cont.)

- Program sends SQL commands to the database by using SQLExecDirect
- Result tuples are fetched using SQLFetch()
- SQLBindCol() binds C language variables to attributes of the query result
 - When a tuple is fetched, its attribute values are automatically stored in corresponding C variables.
 - Arguments to SQLBindCol()
 - ODBC stmt variable, attribute position in query result
 - The type conversion from SQL to C.
 - The address of the variable.
 - For variable-length types like character arrays,
 - The maximum length of the variable
 - Location to store actual length when a tuple is fetched.
 - Note: A negative value returned for the length field indicates null value
- Good programming requires checking results of every function call for errors; we have omitted most checks for brevity.

Database System Concepts - 5th Edition, June 15, 2005 4.33 ©Silberschatz, Korth and Sudarshan

ODBC Code (Cont.)

```

Main body of program
char branchname[80];
float balance;
int lenOut1, lenOut2;
HSTMT stmt;
SQLAllocStmt(conn, &stmt);
char * sqlquery = "select branch_name, sum (balance)
                  from account
                  group by branch_name";
error = SQLExecDirect(stmt, sqlquery, SQL_NTS);
if (error == SQL_SUCCESS) {
    SQLBindCol(stmt, 1, SQL_C_CHAR, branchname, 80,
               &lenOut1);
    SQLBindCol(stmt, 2, SQL_C_FLOAT, &balance, 0,
               &lenOut2);
    while (SQLFetch(stmt) >= SQL_SUCCESS) {
        printf (" %s %g\n", branchname, balance);
    }
    SQLFreeStmt(stmt, SQL_DROP);
}

```

Database System Concepts - 5th Edition, June 15, 2005 4.34 ©Silberschatz, Korth and Sudarshan

More ODBC Features

- **Prepared Statement**
 - SQL statement prepared: compiled at the database
 - Can have placeholders: E.g. insert into account values(?, ?, ?)
 - Repeatedly executed with actual values for the placeholders
- **Metadata features**
 - finding all the relations in the database and
 - finding the names and types of columns of a query result or a relation in the database.
- By default, each SQL statement is treated as a separate transaction that is committed automatically.
 - Can turn off automatic commit on a connection
 - SQLSetConnectOption(conn, SQL_AUTOCOMMIT, 0)
 - transactions must then be committed or rolled back explicitly by
 - SQLTransact(conn, SQL_COMMIT) or
 - SQLTransact(conn, SQL_ROLLBACK)

Database System Concepts - 5th Edition, June 15, 2005 4.35 ©Silberschatz, Korth and Sudarshan

ODBC Conformance Levels

- Conformance levels specify subsets of the functionality defined by the standard.
 - Core
 - Level 1 requires support for metadata querying
 - Level 2 requires ability to send and retrieve arrays of parameter values and more detailed catalog information.
- SQL Call Level Interface (CLI) standard similar to ODBC interface, but with some minor differences.

Database System Concepts - 5th Edition, June 15, 2005 4.36 ©Silberschatz, Korth and Sudarshan

JDBC

- JDBC is a Java API for communicating with database systems supporting SQL
- JDBC supports a variety of features for querying and updating data, and for retrieving query results
- JDBC also supports metadata retrieval, such as querying about relations present in the database and the names and types of relation attributes
- Model for communicating with the database:
 - Open a connection
 - Create a "statement" object
 - Execute queries using the Statement object to send queries and fetch results
 - Exception mechanism to handle errors

Database System Concepts - 5th Edition, June 15, 2005 4.37 ©Silberschatz, Korth and Sudarshan

JDBC Code

```

public static void JDBCexample(String dbid, String userid, String passwd)
{
    try {
        Class.forName ("oracle.jdbc.driver.OracleDriver");
        Connection conn = DriverManager.getConnection(
            "jdbc:oracle:thin:@aura.bell-labs.com:2000:bankdb", userid, passwd);
        Statement stmt = conn.createStatement();
        ... Do Actual Work ...
        stmt.close();
        conn.close();
    }
    catch (SQLException sqle) {
        System.out.println("SQLException : " + sqle);
    }
}

```

Database System Concepts - 5th Edition, June 15, 2005 4.38 ©Silberschatz, Korth and Sudarshan

JDBC Code (Cont.)

- Update to database

```

try {
    stmt.executeUpdate( "insert into account values
('A-9732', 'Perryridge', 1200)");
} catch (SQLException sqle) {
    System.out.println("Could not insert tuple. " + sqle);
}

```
- Execute query and fetch and print results

```

ResultSet rset = stmt.executeQuery( "select branch_name,
avg(balance)
                                from account
                                group by branch_name");

while (rset.next()) {
    System.out.println(
        rset.getString("branch_name") + " " + rset.getFloat(2));
}

```

Database System Concepts - 5th Edition, June 15, 2005 4.39 ©Silberschatz, Korth and Sudarshan

JDBC Code Details

- Getting result fields:
 - `rs.getString("branchname")` and `rs.getString(1)` equivalent if **branchname is the first argument of select result.**
- Dealing with Null values

```

int a = rs.getInt("a");
if (rs.wasNull()) Systems.out.println("Got null value");

```

Database System Concepts - 5th Edition, June 15, 2005 4.40 ©Silberschatz, Korth and Sudarshan

Procedural Extensions and Stored Procedures

- SQL provides a **module** language
 - Permits definition of procedures in SQL, with if-then-else statements, for and while loops, etc.
 - more in Chapter 9
- Stored Procedures
 - Can store procedures in the database
 - then execute them using the **call** statement
 - permit external applications to operate on the database without knowing about internal details
- These features are covered in Chapter 9 (Object Relational Databases)

Database System Concepts - 5th Edition, June 15, 2005 4.41 ©Silberschatz, Korth and Sudarshan

Functions and Procedures

- SQL:1999 supports functions and procedures
 - Functions/procedures can be written in SQL itself, or in an external programming language
 - Functions are particularly useful with specialized data types such as images and geometric objects
 - Example: functions to check if polygons overlap, or to compare images for similarity
 - Some database systems support **table-valued functions**, which can return a relation as a result
- SQL:1999 also supports a rich set of imperative constructs, including
 - Loops, if-then-else, assignment
- Many databases have proprietary procedural extensions to SQL that differ from SQL:1999

Database System Concepts - 5th Edition, June 15, 2005 4.42 ©Silberschatz, Korth and Sudarshan

SQL Functions

- Define a function that, given the name of a customer, returns the count of the number of accounts owned by the customer.

```
create function account_count (customer_name varchar(20))
returns integer
begin
  declare a_count integer;
  select count (*) into a_count
  from depositor
  where depositor.customer_name = customer_name
  return a_count;
end
```
- Find the name and address of each customer that has more than one account.

```
select customer_name, customer_street, customer_city
from customer
where account_count (customer_name) > 1
```

Database System Concepts - 5th Edition, June 15, 2005 4.43 ©Silberschatz, Korth and Sudarshan

Table Functions

- SQL:2003 added functions that return a relation as a result
- Example: Return all accounts owned by a given customer

```
create function accounts_of (customer_name char(20))
returns table (
  account_number char(10),
  branch_name char(15),
  balance numeric(12,2))

return table
(select account_number, branch_name, balance
from account
where exists (
  select *
  from depositor
  where depositor.customer_name = accounts_of.customer_name
  and depositor.account_number = account.account_number))
```

Database System Concepts - 5th Edition, June 15, 2005 4.44 ©Silberschatz, Korth and Sudarshan

Table Functions (cont'd)

- Usage

```
select *
from table (accounts_of ('Smith'))
```

Database System Concepts - 5th Edition, June 15, 2005 4.45 ©Silberschatz, Korth and Sudarshan

SQL Procedures

- The *author_count* function could instead be written as procedure:

```
create procedure account_count_proc (in title varchar(20),
out a_count integer)
begin
  select count(author) into a_count
  from depositor
  where depositor.customer_name = account_count_proc.customer_name
end
```
- Procedures can be invoked either from an SQL procedure or from embedded SQL, using the **call** statement.

```
declare a_count integer;
call account_count_proc ('Smith', a_count);
```

Procedures and functions can be invoked also from dynamic SQL
- SQL:1999 allows more than one function/procedure of the same name (called name **overloading**), as long as the number of arguments differ, or at least the types of the arguments differ

Database System Concepts - 5th Edition, June 15, 2005 4.46 ©Silberschatz, Korth and Sudarshan

Procedural Constructs

- Compound statement: **begin ... end**,
 - May contain multiple SQL statements between **begin** and **end**.
 - Local variables can be declared within a compound statements
- While** and **repeat** statements:

```
declare n integer default 0;
while n < 10 do
  set n = n + 1
end while

repeat
  set n = n - 1
until n = 0
end repeat
```

Database System Concepts - 5th Edition, June 15, 2005 4.47 ©Silberschatz, Korth and Sudarshan

Procedural Constructs (Cont.)

- For** loop
 - Permits iteration over all results of a query
 - Example: find total of all balances at the Perryridge branch

```
declare n integer default 0;
for r as
  select balance from account
  where branch_name = 'Perryridge'
do
  set n = n + r.balance
end for
```

Database System Concepts - 5th Edition, June 15, 2005 4.48 ©Silberschatz, Korth and Sudarshan

Procedural Constructs (cont.)

- Conditional statements (**if-then-else**)
E.g. To find sum of balances for each of three categories of accounts (with balance <1000, >=1000 and <5000, >= 5000)

```

if r.balance < 1000
  then set l = l + r.balance
elseif r.balance < 5000
  then set m = m + r.balance
else set h = h + r.balance
end if

```
- SQL:1999 also supports a **case** statement similar to C case statement
- Signaling of exception conditions, and declaring handlers for exceptions

```

declare out_of_stock condition
declare exit handler for out_of_stock
begin
...
.. signal out-of-stock
end

```

 - The handler here is **exit** -- causes enclosing **begin..end** to be exited
 - Other actions possible on exception

External Language Functions/Procedures

- SQL:1999 permits the use of functions and procedures written in other languages such as C or C++
- Declaring external language procedures and functions

```

create procedure account_count_proc(in customer_name varchar(20),
                                   out count integer)
language C
external name '/usr/avi/bin/account_count_proc'

create function account_count(customer_name varchar(20))
returns integer
language C
external name '/usr/avi/bin/author_count'

```

Database System Concepts - 5th Edition, June 15, 2005 4.50 ©Silberschatz, Korth and Sudarshan

External Language Routines (Cont.)

- Benefits of external language functions/procedures:
 - more efficient for many operations, and more expressive power
- Drawbacks
 - Code to implement function may need to be loaded into database system and executed in the database system's address space
 - risk of accidental corruption of database structures
 - security risk, allowing users access to unauthorized data
 - There are alternatives, which give good security at the cost of potentially worse performance
 - Direct execution in the database system's space is used when efficiency is more important than security

Database System Concepts - 5th Edition, June 15, 2005 4.51 ©Silberschatz, Korth and Sudarshan

Security with External Language Routines

- To deal with security problems
 - Use **sandbox** techniques
 - that is use a safe language like Java, which cannot be used to access/damage other parts of the database code
 - Or, run external language functions/procedures in a separate process, with no access to the database process' memory
 - Parameters and results communicated via inter-process communication
- Both have performance overheads
- Many database systems support both above approaches as well as direct executing in database system address space

Recursion in SQL

- SQL:1999 permits recursive view definition
- Example: find all employee-manager pairs, where the employee reports to the manager directly or indirectly (that is manager's manager, manager's manager's manager, etc.)

```

with recursive empl (employee_name, manager_name) as (
  select employee_name, manager_name
  from manager
 union
  select manager.employee_name, empl.manager_name
  from manager, empl
  where manager.manager_name = empl.employee_name)
select *
from empl

```

This example view, *empl*, is called the *transitive closure* of the *manager* relation

Database System Concepts - 5th Edition, June 15, 2005 4.53 ©Silberschatz, Korth and Sudarshan

The Power of Recursion

- Recursive views make it possible to write queries, such as transitive closure queries, that cannot be written without recursion or iteration.
 - Intuition: Without recursion, a non-recursive non-iterative program can perform only a fixed number of joins of *manager* with itself
 - This can give only a fixed number of levels of managers
 - Given a program we can construct a database with a greater number of levels of managers on which the program will not work
 - The next slide shows a *manager* relation and each step of the iterative process that constructs *empl* from its recursive definition. The final result is called the *fixed point* of the recursive view definition.
- Recursive views are required to be *monotonic*. That is, if we add tuples to *manager* the view contains all of the tuples it contained before, plus possibly more

Database System Concepts - 5th Edition, June 15, 2005 4.54 ©Silberschatz, Korth and Sudarshan

Example of Fixed-Point Computation

| <i>employee_name</i> | <i>manager_name</i> |
|----------------------|---------------------|
| Alon | Barinsky |
| Barinsky | Estovar |
| Corbin | Duarte |
| Duarte | Jones |
| Estovar | Jones |
| Jones | Klinger |
| Rensal | Klinger |

| <i>Iteration number</i> | <i>Tuples in empl</i> |
|-------------------------|---|
| 0 | |
| 1 | (Duarte), (Estovar) |
| 2 | (Duarte), (Estovar), (Barinsky), (Corbin) |
| 3 | (Duarte), (Estovar), (Barinsky), (Corbin), (Alon) |
| 4 | (Duarte), (Estovar), (Barinsky), (Corbin), (Alon) |

Advanced SQL Features**

- Create a table with the same schema as an existing table:
create table temp_account like account
- SQL:2003 allows subqueries to occur *anywhere* a value is required provided the subquery returns only one value. This applies to updates as well
- SQL:2003 allows subqueries in the **from** clause to access attributes of other relations in the **from** clause using the **lateral** construct:
select customer_name, num_accounts
from customer, lateral (
 select count(*)
 from account
 where account.customer_name = customer.customer_name)
as this_customer (num_accounts)

Database System Concepts - 5th Edition, June 15, 2005 4.56 ©Silberschatz, Korth and Sudarshan

Advanced SQL Features (cont'd)

- Merge construct allows batch processing of updates.
- Example: relation *funds_received* (*account_number*, *amount*) has batch of deposits to be added to the proper account in the *account* relation
merge into account as A
using (select *
 from funds_received as F)
on (A.account_number = F.account_number)
when matched then
 update set balance = balance + F.amount
